### **ABSTRACT**

The National Aeronautics and Space Administration (NASA) envisions a 21st-century program of space and Farth science missions that will use revolutionary new technologies and architectures to reduce costs and enhance the capabilities of missions. Needed will be advanced miniaturized instruments, microspacecraft, and "intelligent" flight systems to reduce the costs and personnel involved in operations monitoring. The goal of NASA's New Millennium Program (NMP) is to enable frequent, affordable, ca pable missions of the future by identifying, developing, and flight validating key technologies. Targeting technologies in development by NASA's field centers, government agencies, nonprofit organizations, and academia - and establishing partnerships among these entities to develop the technological gies and implement the flights - NMP will enable future missions to avoid the risk of "first use," and at the same time take advantage of advanced capabilities. Teaming approaches and new management structures are also a part of NMP, with the aim of demonstrating effective operations methods for high technology organizations in the post-2000 environment. The accelerated infusion of advanced, enabling technologies and the application of new ways of doing business will encourage development and open the way to the 21st century.

This paper is declared a work of the U.S. Government and is not subject to copyright protection in the United States.

### THE NEW MILLENNIUM CONCEPT

NASA's vision for its space and Faith science programs of the 21st century is bold: Exciting, affordable scientific missions with highly focused objectives will be launched frequently, with numerous "microspacecraft" carrying advanced min iaturized instruments returning a continuous flow of information from space to Farth. Using revolu tionary new technologies and architectures to reduce the costs and enhance the capabilities of these missions, the United States will gain important data about Faith, the solar system, and the universe; new insights reaped from the programs will stimulate public interest and provide new learning opportunities for students at all levels. The wealth of new scientific information and its widespread dissemination - combined with the rapid development, deployment, and transfer of new technology - will maintain the United States' global leadership in space science and technology.

The goal of NASA's New Millennium Program (NMP) is to enable frequent, affordable, capable scientific missions in the 21st century by identifying, developing, and flight validating key technologies that can significantly contribute to

lowering life-cycle costs while increasing scientific returns. Breakthrough technologies selected from the existing "pipeline" that is formed by and flows through current technology programs of NASA, other government agencies, nonprofit institutions, and academia will be developed in partnership among these organizations. Critical technologies will be validated through (ledic-sled spaceflights so that future science missions can take advantage of these technologies without having to assume the risks inherent in their first use.

In addition to developing and validating key enabling technologies, NMP will pioneetnew ways of partnering among industry, nonprofit organizations, academic institutions, and NASA and other government agencies by developing and implementing illlm'alive management practices. '1 his will advance the competitive edge of the nation's high-technology organizations as we move into the 21st century.

NMP is being implemented in partnership among NASA's Office of Space Science, Office of Mission to Planet Farth, and Office of Space Access and "1 echnology, and is managed by the Jet Propulsion 1 aboratory (J)'1) of the California Institute of '1 echnology. Several other NASA field centers are participating in the program as validation-flight implementers and/or as technology providers. Goddard Space Flight Center in particular will contribute significantly in the development and execution of the Farth science technology - validation flights.

SCIENTIFIC EXPLORATION IN THE NEXT CINTURY

Attessential element of the NMP technology-validation process is a clearunderstanding of the envisioned mode of cat rying outscientific exploration in the next century. During the 20th century, specifically in the 1960s and 1970s,

NASA's space science program focused primarily on developing and implementing solitary robotic explorers in which electronics were mainly discrete-composed based. As a spacecraft's functionality increased, so did its number of components. Since discrete-component reliability was limited, redundancy was used to allow the multiyear flights to last their required lifetime. Size, weight, power, design, development, and cost all grew accordingly with the spacecraft's increasing capabilities, Round-trip communications times dictated the nature and expansion of onboard autonomy and the types of fault protection and correction. Since launch-vehicle capability was very high, launching these spacecraft - which weighed thousands of kilograms - was well within our means. With transportation ability to visit other planets well irr hand, it became cost effective to try to maximize the science return from each mission, since spacecraft were launched infrequently. This, in turn, led to the development of spacecraft with capabilities of executing 20 or more science experiments. For example, the plan etary exploration program, with its in itial focus on reconnaissance and preliminary characterization of the solar system, has sent out single or dual spacecraft with complex complements of itls1111111c111s togather fundamental information about planetary surfaces, atmospheres, magnetospheres, satellites, rings, and the interplanetary environment.

Continued use of individual or dual spacecraft to expand our exploration frontiers is still expected to be an important element of the space science program of the future. Astronomers will use individual spacecraft to continue observations in all regions of the electromagnetic spectrum; space physicists will employ individual spacecraft to study the response of the Faith's atmosphere to sola radiative output; planetary scientists will use

individual spacecraft to explore Pluto, the Kuiper Belt, and (lie universe beyond. Individual spacecraft can also be used to characterize the surface of Mercu ry and to study and monitor the outer planets and their satellites. Through a series of in dividual launches, individual spacecraft can also be used to survey multiple asteroids and comets and to provide samples from a range of possible objects targeted for study.

As we approach the 2.1 st century, however, the nation's fiscal environment, our technological capabilities, and our relative maturity in terms of understanding Farth and the solar system all point to a new paradigm: one that capitalizes on new technologies to enable frequent launches of low-mass, low-cost spacecraft, each 0[ which addresses a focused set of scientific questions.

NASA envisions the deployment of multiple spacecraft to analyze the more dynamic systems and processes in our solar system and beyond. Single-point measurements will be insufficient to address questions concerning complex, dynamic systems; these questions would best be answered throughtime-correlated measurements at multiple locations. For example, in using just a single spacecraft, it is impossible to discern with sufficient accuracy the extent to which solartidal activity affects changes in planetary atmospheric structures. The science community has for some time supported the concept of using networks of landers to examine interior planetary dynamics and structures as a means of determining the size and nature of planetary cores and geologic activities. Constellations of spacecraft may prove to be the most cm-effective way to get the comprehersive information needed to determine solar variability and its effects on Faith, in order to further investigate global change and natural hazards.

Two examples of exciting 21st-century missions that will be enabled by NM P's technology-valida tion lights are comet sample return missions and extrasolar planetary imaging missions. Cornet sample return missions form a category of highpriority missions that are focused on our solar system, grouped within the unifying theme of "Our Planetary Neighbors." Characterization of the primitive materials of which comets are composed will shed light on the origin and evolution Of the solar system. "1 he envisioned mission implementation includes the selection of an appropriatelanding site following an orbital survey, in situ study, selection and collection of local samples, and return of samples to Farth through direct atmospheric Cutry. The second type of misan extrasolar planetary imaging mission

will explore the universe using a flee-flyill~, in terferometer: a constellation of spacecraft capable of imaging extrasolar planets. Such a constellation could detect harth-like planets and should provide information clarifying the origin and evolution of planetary systems in general.

### THENEW MILLE NNI(Jh4]'IKX>I:Ah41'LAN

Fulfilling this vision for the future will require new capabilities to reduce the costs O[ develop ment, launch, and operations; to increase mission frequency; and to enhance scientific- observing and data-gathering capabilities. Capable microspacecraft with miniaturized instruments will be called [et, with a move toward use of smaller, less costly launch vehicles. Also, shorter flight times and "intelligent" flight systems will be required in order to reduce the number of people needed to operate our spacecraft. Through a series of technology-driven missions, NMP will provide at Lorderly transition to this new paradigm

by flight validating, those technologies that contribute most significantly to establishment of the paradigm.

The basic plan is relatively simple and straightforward: NMP will first identify shortcomings in current technology that prevent us from immediately carrying out our vision of scientific exploration. Breakthrough technologies providing affordable solutions will then be sought from the technology community, and [hose that are found to most significantly contribute to achieving our goal of frequent launches of exciting, affordable space and Farth science missions will be selected as high-priority candidates for development and validation.

THENEW MILLENNIUM
SCHNOF WORKING GROUP

A New Millennium Science Working Group (SWG) has been chartered to help the program both in developing a vision of scientific exploration in the next century and in identifying the capabilities required to fulfill this vision. The SWG has listed the key scientific challenges facing the space and Farth sciences community as we enter the next century, emphasizing those challenges that are particularly amenable to solutions using small, capable spacecraft. The SWG has also helped in cataloging the kinds of missions we can expect to fly in the post-2000 era that might address these scientific challenges, while working closely with the NMI' team to evaluate which capabilities the.sc missions require, and using this information to identify and evaluate advancedtechnology candidates that can provide these capabilities.

The SWG is expected to remain active through the duration of the New Millennium Program to ensure that the program stays focused cm achieving our scientific vision of exploration for the next century.

SHECHING THEIR INON LOGIESTOR FIGHTS

NM]' will emphasize technologies that significantly contribute to reducing the costs, increasing the frequency, and enhancing the scientific capability of future science missions. It will sponsor revolutionary technology advances that of fersignificant new opportunities for future missions but which have traditionally been difficult to incorporate into science missions because of the inherently high risk associated with developing, qualifying, and validating new technologies.

Initial evaluation of the capabilities required to achieve our scientific vision has indicated a need to focus on \$\infty\$ veral key technology areas. These are:

Autonomy: Technologies supporting revolutionary advances in autonomous spacecraft operations.

Microelectronic Systems: '1 echnologies supporting revolutionary advances in microelectronics in flight computing, command and data handling, guidance and navigation, and power subsystems Instruments and Microelectrom echanical Systems (MEMS): Technologies supporting revolutionary advances in Iljicle)ill<tilljilcl-it<, miniaturized instruments, novel instrument designs, and interferometric systems, using MEMS advances where appropriate.

Communications Systems: Technologies supporting revolutionary advances in transmitters, amplifiers, receivers, antennas, switches, and transmission lines, with frequencies ranging from traditional RF bands (S, X, Ka) and beyond, to optical wavelengths.

Modular and Multifunctional Systems: "1 echnologies supporting revolutionary advance in a number of

areas including, but not limited to, structural, mechanisms, thermal control, and propulsion. Integrated Product Development Teams (IPDTs) have been formed to identify advanced-technology candidates currently under development in these key areas. Initially, the IPDTs are being colled by a technology expert from JPL and an expert from another NASA center. Industry, academia, NASA and other government agencies, and nonprofit organizations are all expected to participate as IPDT members. Solicitations for team participation will be issued periodically throughout the duration of the program.

"1 he IPDTs will establish and maintain "road maps" - phased technology-development plans needed to achieve required capabilities - for each key technology area. The teams will determine costs associated with advancing each technology to the point where it can be flight validated. The IPDTs (or certain subsets of these teams) are expected to facilitate the final development of the technologies determined to be of most benefit toward achieving NMI' objectives, and infuse them into the validation flights.

## IDINTHICATION 01 CANDIDATE. NMP MISSION SETS

The NMP Architecture Development Team, using JPL's Project Design Center, is beginning to evaluate candidate mission sets. Each mission set is composed of three to four technology-validation flights expected to take place bet ween 1997 and 2000; each flight is structured to validate a selected suite of advanced technologies. The Aichitecture Development Team, using technology development plan inputs from the 11'1>"1"s, will evaluate a range of mission set options to determine the extent to which they meet NMP objectives.

While the primary purpose of each flight will be to validate a given suite of advanced technologies, the mission itself will be designed to be of scientific value and of sufficient complexity so as to fully exercise the technologies to perform as they would in future scientific missions. I inking the primary technology objectives with a secondary scientific objective will assure close and continued interaction between the technology developers and the scientific community throughout the design, development, and operations phases of the missions. This is critical to ensuring that, once validated, the technologies will be readily incorporated into future scientific missions.

NASA I headquarters will make the decision to proceed with the development of a specific mission set, applying a number of metrics in [heir evaluation. These metrics include assessing the overall technology richness of the mission and its scient ific value, as well as the future commercialization potential of the technologies. Additionally, life-cycle cost comparisons - i.e., comparing the cost of missions employing new technologies vet - sus those that do not - will be established to clearly illustrate the long-term benefits of the program

It should be noted that not all technologies will require flight validation, since in some cases ground validation will suffice, Also, an NMP technology validation may take advantage of non-NMP flight opportunities when an appropriate opportunity exists.

### VALIDATION FIGHT TEAMS

After NASA 1 leadquarters decides to proceed with a given mission set, Flight Teams will be established to implement each technology-vali(lation flight. Each Flight Team will include members from industry, academia, and govern -

ment - with industry anti academia participation being formally solicited - and will work closely with the IPDTs and the NMI' Architecture Development Team to design the technology-validation flights in a manner compatible with the technology-readiness dates, launch -schedule, and funding.

JPL will use its Flight System Testbed (I'S-I-) to support mission development as required. The FST allows the Flight Teams to rapidly evaluate and test new technologies by creating a virtual (simulated) spacecraft in which system-level evaluation of components can be carried out very early in the development cycle. In addition to spacecraft hardware and software validation, the FST also accommodates ground data system development and end-lo-end project simulation and testing. During spacecraft development, designers can bring one or several subsystems, or even an entire small spacecraft, to the FST for testing.

### NEW MILLINNIUM PARTNERSHIPS

innovative partnerships among industry, nonprofit organizations, academic institutions, and NASA and other government agencies are integral to NMP's success. Partners will be involved in evet-y aspect of the program. They will participate as IPDT members, identifying and providing breakthrough technologies appropriate for NMI' technology-validation flights, and as Flight Team members, assuming a major role in developing and fabricating components, subsystems, systems, and spacecraft for the flight. They will also participate through the duration of mission operations and support data processing. These partnerships will create an environment conducive to the transfer of technologies and expertise to those expected to be the primary spacecraft providers of the future.

NMP expects to capitalize on the existing NASA Small Business Innovative Research (SBIR) program to focus small business technology-development efforts in support of NMI' objectives.

Consequently, members of the SBIR program are also expected to form partnerships within NMI'.

NMI' partnerships are expected to evolve over the course of the program. New team members will be brought on board as new technologies ate identified and new validation missions are implemented. A "Council" will be instituted to recommend strategies and activities to NMI' that will maximize the benefits and competitive advantages of these partnerships.

#### Summary

Investing in the New Millennium Program is investing in the future, fulfilling the vision of future scientific exploration depends on new capabilities to reduce costs of development, launch, and operations; to increase mission frequency; and to enhance scientific-observing and data-gathering capabilities. Smaller launch vehicles and capable microspacecraft and microinstruments will be required, and fewer people will be needed for operations because of shorter flight times and the use of "intelligent" flight systems having increased autonomy.

NASA's vision for the 21st century is a compelling one, incorporating access to new frontiers and greatly expanding our scientific understanding. With networks of landers on Mars and Venus, clusters of probes mapping planetary ionospheres and magnetospheres, spacecraft returning samples from asteroids and comets, and constellations of spacecraft peering into neighboring solar systems, we will truly be able to create a virtual human presence in space. The concepts of fleets of individual spacecraft, constellations, and

networks of spacecraft arc allowing new mission approaches for the future to evolve. We need multiple spacecraft to go beyond our initial solar system reconnaissance and to more completely characterize dynamic systems in the way we ate able to do on the surface of Earth.

An accelerated infusion of new, enabling technologies and new ways of doing business are integral to achieving these goals. The New Millennium Program, with its emphasis on strong partnerships among government, academia, and industry, and between the science and technology communities, will provide an environment conducive to rapid technology development and flight validation. These benefits, along with the substantial benefits to the science community, herald new ways of doing business in the 21st century.

### Acknowledgment

The research described in this paper was carried out by the Jet Propulsion Laboratory, California Institute of '1 echnology, under a contract with the National Aeronautics and Space Administration.
